We discuss a generalized Schrödinger operator in $L^2(\mathbb{R}^d)$, $d=2,3$, with an attractive singular interaction supported by a $(d-1)$-dimensional hyperplane and a finite family of points. It can be regarded as a model of a leaky quantum wire and a family of quantum dots if $d=2$, or surface waves in presence of a finite number of impurities if $d=3$. We analyze the discrete spectrum, and furthermore, we show that the resonance problem in this setting can be explicitly solved; by Birman-Schwinger method it is cast into a form similar to the Friedrichs model.

1 Introduction

The subject of this paper is a nonrelativistic quantum Hamiltonian in $L^2(\mathbb{R}^d)$, $d=2,3$, with a singular interaction supported by a set consisting of two parts. One is a flat manifold of dimension $d-1$, i.e. a line for $d=2$ and a plane for $d=3$, the other is a finite family of points situated in general in the complement to the manifold. The corresponding generalized Schrödinger operator can be formally written as

$$-\Delta - \alpha \delta(x - \Sigma) + \sum_{i=1}^{n} \tilde{\beta}_i \delta(x - y^{(i)}),$$

(1.1)
where $\alpha > 0$, $\Sigma := \{(x_1, 0); x_1 \in \mathbb{R}^{d-1}\}$, and $y^{(i)} \in \mathbb{R}^d \setminus \Sigma$; the formal coupling constants of the $d$-dimensional $\delta$ potentials are marked by tildas because they are not the proper parameters to be used; we will discuss this point in more detail below.

The first question to be posed is about a physical significance of such a Hamiltonian. Operators of the type (1.1) or similar have been studied recently with the aim to describe nanostructures which are “leaky” in the sense that they do not neglect quantum tunneling – cf. [7, 8, 9, 10, 11, 12, 13] and references therein. In this sense we can regard the present model with $d = 2$ as an idealized description of a quantum wire and a collection of quantum dots which are spatially separated but close enough to each other so that electrons are able to pass through the classically forbidden zone separating them. Similarly the three-dimensional case can be given interpretation as a description of surface states under influence of a finite number of point perturbations.

We will ask first about the discrete spectrum of the Hamiltonian (1.1). It will be demonstrated to be always nonempty and properties of the eigenvalues in terms of the model parameters will be derived, which complements the existing knowledge about the discrete spectrum of such generalized Schrödinger operators derived in the mentioned papers and earlier, e.g., in [3].

Our main concern in this paper, however, is the scattering within our model, in particular, the question about existence of the resonances. It is obvious that this is an important problem for generalized Schrödinger operators with the interaction supported by a non-compact manifold of a lower dimension, of which a little is known at present. The simple form of the interaction support, $\Sigma \cup \Pi$ with $\Pi := \{y^{(i)}\}$, will allow us to analyze the scattering for the operator (1.1). We will achieve that by using the generalized Birman-Schwinger method which makes it possible to convert the original PDE problem into a simpler equation which in the present situation is in part integral, in part algebraic. The main insight is that the method works not only for the discrete spectrum but it can be used also to find singularities of the analytically continued resolvent. The problem can be then reduced to a finite rank perturbation of eigenvalues embedded in the continuous spectrum, i.e. something which calls to mind the celebrated Friedrichs model – cf. [14] or [6, Sec. 3.2].

We will pay most attention to the two-dimensional case. In the next section we will first explain how the operator (1.1) should be properly defined, then we derive a Birman-Schwinger-type expression for its resolvent. Using
this information we discuss in Sec. 3 the discrete spectrum, first for \( n = 1 \), then for a pair of point perturbations showing how embedded eigenvalues due to symmetry may arise, and finally for a general \( n \). In Sec. 4 we tackle the resonance problem using the mentioned analytical continuation of the resolvent. For simplicity we consider only the cases of a single perturbation, where the resonance width is found to be exponentially in terms of the distance between the line and the point, and of a pair of them to illustrate how resonances can arise from symmetry breaking. We will also treat the same problem with \( n = 1 \) from other point of views: as a scattering of a particle transported along the line and as a decaying unstable system. Finally in Sec. 5 we investigate the three-dimensional case. Since the analysis is similar, we restrict ourselves to describing the features which are different for \( d = 3 \).

2 The Hamiltonian for \( d = 2 \)

2.1 Definition of Hamiltonian

If \( d = 2 \) the interaction is supported by \( \Sigma \cup \Pi \) with \( \Sigma := \{(x_1, 0); x_1 \in \mathbb{R}\} \) and \( \Pi := \{y^{(i)}\}_{i=1}^{n}, \) where \( y^{(i)} \in \mathbb{R}^2 \setminus \Sigma. \) For simplicity we also put \( L^2 \equiv L^2(\mathbb{R}^2). \) The most natural way to find a self-adjoint realization of the formal expression (1.1) is to construct the Laplace operator with appropriated boundary conditions on \( \Sigma \cup \Pi. \) To this aim let us consider functions \( f \in W^{2,2}_{\text{loc}}(\mathbb{R}^2 \setminus (\Sigma \cup \Pi)) \cap L^2 \) which are continuous on \( \Sigma. \) For a sufficiently small positive number \( \rho \) the restriction \( f \upharpoonright_{C_{\rho,i}} \) to the circle \( C_{\rho,i} := C_{\rho}(y^{(i)}) := \{q \in \mathbb{R}^2: |q - y^{(i)}| = \rho\} \) is well defined. Furthermore, we will say that function \( f \) belongs to \( D(\dot{H}_{\alpha,\beta}) \) if and only if the following limits,

\[
\Xi_i(f) := \lim_{\rho \to 0} \frac{1}{\ln \rho} f \upharpoonright_{C_{\rho,i}}, \quad \Omega_i(f) := \lim_{\rho \to 0} [f \upharpoonright_{C_{\rho,i}} + \Xi_i(f) \ln \rho]
\]

for \( i = 1, \ldots, n, \) and

\[
\Xi_{\Sigma}(f)(x_1) := \frac{\partial x_2 f(x_1, 0+)}{\partial x_2} - \frac{\partial x_2 f(x_1, 0-)}{\partial x_2}, \quad \Omega_{\Sigma}(f)(x_1) := f(x_1, 0)
\]

are finite and satisfy the relations

\[
2\pi \beta_i \Xi_i(f) = \Omega_i(f), \quad \Xi_{\Sigma}(f)(x_1) = -\alpha \Omega_{\Sigma}(f)(x_1), \quad (2.1)
\]

where \( \beta_i \in \mathbb{R}. \) For simplicity we put \( \beta \equiv (\beta_1, \ldots, \beta_n) \) in the following. Finally, we define the operator \( \dot{H}_{\alpha,\beta} : D(\dot{H}_{\alpha,\beta}) \to L^2 \) acting as

\[
\dot{H}_{\alpha,\beta} f(x) = -\Delta f(x) \quad \text{for} \quad x \in \mathbb{R}^2 \setminus (\Sigma \cup \Pi).
\]
The integration by parts shows that $\tilde{H}_{\alpha,\beta}$ is symmetric; let $H_{\alpha,\beta}$ denote its closure. To check that the latter is self-adjoint let us consider an auxiliary operator $\tilde{H}_\alpha$ defined as the Laplacian with boundary condition (2.1) and the additional restriction $\Xi_i(f) = \Omega_i(f) = 0$ for $f \in D(\tilde{H}_\alpha)$ and all $i = 1, \ldots, n$. It is straightforward to see that the operator $\tilde{H}_\alpha$ is symmetric with deficiency indexes $(n, n)$, and moreover, that the first equation of (2.1) determines $n$ symmetric linearly independent boundary conditions; thus using the standard result [5, Thm. XII.30] we conclude that $H_{\alpha,\beta}$ is self-adjoint.

**Remarks 2.1**

(a) The parameters determining the point interactions clearly differ from the $\tilde{\beta}_i$ used in (1.1), for instance, absence of such an interaction formally means that $\beta_i = \infty$.

(b) With a later purpose on mind we introduce some notations. Let $H_\beta := H_{0,\beta}$ be defined as the Laplacian with the point interactions only. Furthermore, let $\tilde{H}_\alpha$ denote the Laplace operator with the point perturbations (supported by $\Pi$) removed; this operator formally corresponds to $H_{\alpha,\infty}$. It is well known that both these operators are self-adjoint – cf. [2].

### 2.2 The resolvent

To perform spectral analysis of $H_{\alpha,\beta}$ we will need its resolvent. Given $z \in \rho(-\Delta) = \mathbb{C} \setminus [0, \infty)$ denote by $R(z) = (-\Delta - z)^{-1}$ the free resolvent, which is well known to be an integral operator in $L^2$ with the kernel

$$G_z(x, x') = \frac{1}{(2\pi)^2} \int_{\mathbb{R}^2} e^{i p (x - x')} \frac{d^2 p}{p^2 - z} = \frac{1}{2\pi} K_0(\sqrt{-z}|x - x'|), \quad (2.2)$$

where $K_0(\cdot)$ is the Macdonald function and the function $z \mapsto \sqrt{z}$ has conventionally a cut at the positive halfline. Moreover, denote by $R(z)$ the unitary operator defined as $R(z)$ but acting from $L^2$ to $W^{2,2} \equiv W^{2,2}(\mathbb{R}^2)$.

To construct the resolvent of $H_{\alpha,\beta}$ we will need two auxiliary Hilbert spaces, $\mathcal{H}_0 := L^2(\mathbb{R})$ and $\mathcal{H}_1 := \mathbb{C}^n$, and the corresponding trace maps $\tau_0 : W^{2,2} \to \mathcal{H}_0$ and $\tau_1 : W^{2,2} \to \mathcal{H}_1$ which act as

$$\tau_0 f := f \upharpoonright \Sigma, \quad \tau_1 f := f \upharpoonright \Pi = (f \upharpoonright \{y^{(1)}\}, \ldots, f \upharpoonright \{y^{(n)}\}),$$

respectively; in analogy with the previous section the above notations indicate the appropriate restrictions. By means of $\tau_i$ we can define the canonical embeddings of $R(z)$ to $\mathcal{H}_i$, i.e.

$$R_{iL}(z) = \tau_i R(z) : L^2 \to \mathcal{H}_i, \quad R_{Li}(z) = [R_{iL}(z)]^* : \mathcal{H}_i \to L^2, \quad (2.3)$$
and
\[ R_{ji}(z) = \tau_j R_{Li}(z) : \mathcal{H}_i \to \mathcal{H}_j. \]

To express the resolvent of \( H_{\alpha,\beta} \) we need the operator-valued matrix
\[ \Gamma(z) = [\Gamma_{ij}(z)] : \mathcal{H}_0 \oplus \mathcal{H}_1 \to \mathcal{H}_0 \oplus \mathcal{H}_1, \]
where \( \Gamma_{ij}(z) : \mathcal{H}_j \to \mathcal{H}_i \) are the operators given by
\[ \Gamma_{ij}(z) g := -R_{ij}(z) g \quad \text{for} \quad i \neq j \quad \text{and} \quad g \in \mathcal{H}_j, \]
\[ \Gamma_{00}(z) f := \left[ \alpha^{-1} - R_{00}(z) \right] f \quad \text{if} \quad f \in \mathcal{H}_0, \]
\[ \Gamma_{11}(z) \varphi := \left[ s_{\beta l}(z) \delta_{kl} - G_z(y^{(k)}, y^{(l)})(1 - \delta_{kl}) \right]_{k,l=1}^n \varphi \quad \text{for} \quad \varphi \in \mathcal{H}_1, \]
and \( s_{\beta l}(z) = \beta_l + s(z) := \beta_l + \frac{1}{2\pi}(\ln \sqrt{z} - \psi(1)) \), where \(-\psi(1) \approx 0.577\) is the Euler number – cf. [2, Sec. I.5].

We will also need the inverse of \( \Gamma(z) \). To this aim let us denote by \( \mathcal{D} \) the set of \( z \in \mathbb{C} \) such that \( \Gamma(z) \) is boundedly invertible; as we will see \( \mathcal{D} \) coincides with the resolvent set of \( H_{\alpha,\beta} \). For \( z \in \mathcal{D} \) the operator \( \Gamma_{00}(z) \) is invertible and thus it makes sense to define \( D(z) \equiv D_{11}(z) : \mathcal{H}_1 \to \mathcal{H}_1 \) by
\[ D(z) = \Gamma_{11}(z) - \Gamma_{10}(z) \Gamma_{00}(z)^{-1} \Gamma_{01}(z) \quad (2.4) \]
which is invertible for \( z \in \mathcal{D} \); the above operator will be called the reduced determinant of \( \Gamma \). By a straightforward calculation one can check that the inverse of \( \Gamma(z) \) is given by
\[ [\Gamma(z)]^{-1} : \mathcal{H}_0 \oplus \mathcal{H}_1 \to \mathcal{H}_0 \oplus \mathcal{H}_1, \quad (2.5) \]
with the ”block elements” defined by
\[ [\Gamma(z)]^{-1}_{11} = D(z)^{-1}, \]
\[ [\Gamma(z)]^{-1}_{00} = \Gamma_{10}(z)^{-1} \Gamma_{11}(z) D(z)^{-1} \Gamma_{10}(z) \Gamma_{00}(z)^{-1}, \]
\[ [\Gamma(z)]^{-1}_{01} = -\Gamma_{00}(z)^{-1} \Gamma_{01}(z) D(z)^{-1}, \]
\[ [\Gamma(z)]^{-1}_{10} = -D(z)^{-1} \Gamma_{10}(z) \Gamma_{00}(z)^{-1}; \]
in the above formulae we use notation \( \Gamma_{ij}(z)^{-1} \) for the inverse of \( \Gamma_{ij}(z) \) and \( [\Gamma(z)]^{-1}_{ij} \) for the matrix element of \( [\Gamma(z)]^{-1} \).

With these preliminaries we are ready to state the sought formula for the explicit form of the resolvent of \( H_{\alpha,\beta} \).
Theorem 2.2 For any $z \in \rho(H_{\alpha,\beta})$ with $\text{Im} \, z > 0$ we have

$$R_{\alpha,\beta}(z) \equiv (H_{\alpha,\beta} - z)^{-1} = R(z) + \sum_{i,j=0}^{1} R_{Li}(z)[\Gamma(z)]_{ij}^{-1}R_{jL}(z).$$  \hspace{1cm} (2.6)

Proof. We employ again the vector notation, $\Xi(f) \equiv (\Xi_1(f), \ldots, \Xi_n(f))$ and $\Omega(f) \equiv (\Omega_1(f), \ldots, \Omega_n(f))$. We have to check that $f \in D(H_{\alpha,\beta})$ holds if and only if $f = \tilde{R}_{\alpha,\beta}(z)g$ for some $g \in L^2$, where $\tilde{R}_{\alpha,\beta}(z)$ denotes the operator at the right-hand side of the last equation. Suppose that $f$ is of this form. It belongs obviously to $W_{\text{loc}}^{2,2}(\mathbb{R}^2 \setminus (\Sigma \cup \Pi)) \cap L^2$ because the same is true for all its components. Combining the definitions of $R_{ij}, [\Gamma(z)]_{ij}^{-1}$, and the functionals $\Xi_i$ and $\Omega_i$ introduced above with the asymptotic behaviour of Macdonald function, specifically

$$K_0(\sqrt{-z}) \to - \ln \rho - 2\pi s(z) + \mathcal{O}(\rho) \quad \text{for} \quad \rho \to 0,$$

we arrive at

$$2\pi \Xi(f) = \sum_{i=0}^{1} [\Gamma(z)]_{ii}^{-1} R_{iL}(z)g,$$

$$\Omega(f) = R_{1L}(z)g - \sum_{i=0}^{1} \Gamma_{10}(z)[\Gamma(z)]_{00}^{-1} R_{0L}g - s(z) \sum_{i=0}^{1} [\Gamma(z)]_{ii}^{-1} R_{iL}(z)g.$$

Let us consider separately the components of $\Xi(f), \Omega(f)$ coming from the behaviour of $g$ at the points of the set $\Pi$ and on $\Sigma$, i.e. for $i = 1, 2$, which means to define the vectors $\Xi^i(f) := \frac{1}{2\pi}[\Gamma(z)]_{ii}^{-1} R_{iL}g$ and

$$\Omega^0(f) := \left[ -\Gamma_{10}(z)[\Gamma(z)]_{00}^{-1} - s(z)[\Gamma(z)]_{11}^{-1} \right] R_{0L}g,$$

$$\Omega^1(f) := \left[ 1 - \Gamma_{10}(z)[\Gamma(z)]_{00}^{-1} - s(z)[\Gamma(z)]_{11}^{-1} \right] R_{1L}g.$$

Using the properties of $[\Gamma_{ij}(z)]$ and its inverse it is straightforward to check that $\Omega^i_k(f) = 2\pi \beta_k \Xi^i_k(f)$ holds for $i = 0, 1$ and $k = 1, \ldots, n$; the symbols $\Omega^i_k(f), \Xi^i_k(f)$ mean here the $k$-th component of $\Omega^i(f), \Xi^i(f)$ respectively. Similar calculations yield the relation $\Xi_{\Sigma}(f) = -\alpha \Omega_{\Sigma}(f)$ which shows that $f$ belongs to $D(H_{\alpha,\beta})$, and the converse statement, namely that any function from $D(H_{\alpha,\beta})$ admits a representation of the form $f = \tilde{R}_{\alpha,\beta}(z)g$. To conclude the proof, observe that for a function $f \in D(H_{\alpha,\beta})$ which vanishes on $\Sigma \cup \Pi$ we have $(-\Delta - z)f = g$. Consequently, $\tilde{R}_{\alpha,\beta}(z) = R_{\alpha,\beta}(z)$ is the resolvent of the Laplace operator in $L^2$ with the boundary conditions (2.1). □
2.3 Another form of the resolvent

With a later purpose on mind it is useful to look at the model in question also from another point of view, namely as a point-interaction perturbation of the “line only” Hamiltonian $\tilde{H}_\alpha$. In the same way as above we can check that the resolvent of $\tilde{H}_\alpha$ is the integral operator

$$R_\alpha(z) = R(z) + R_{L0}(z)\Gamma^{-1}_{00}R_{0L}(z)$$  \hspace{1cm} (2.8)

for any given $z \in \rho(\tilde{H}_\alpha) = \mathbb{C}\setminus[-\frac{1}{4} \alpha^2, \infty)$. Define now the operators $R_{\alpha;L1}(z) : \mathcal{H}_1 \to L^2$ and $R_{\alpha;1L}(z) : L^2 \to \mathcal{H}_1$ by

$$R_{\alpha;1L}(z)f = R_\alpha(z)f \upharpoonright_{\Pi} \text{ for } f \in L^2$$  \hspace{1cm} (2.9)

and $R_{\alpha;L1}(z) = R^*_{\alpha;1L}(z)$. The Hamiltonian $H_{\alpha,\beta}$ is obtained by adding a finite number of point perturbations to $\tilde{H}_\alpha$. Consequently, the difference of the resolvents $R_{\alpha,\beta}$ and $R_\alpha$ is given by Krein’s formula

$$R_{\alpha,\beta}(z) = R_\alpha(z) + R_{\alpha;L1}(z)\Gamma_{\alpha;11}(z)^{-1}R_{\alpha;1L}(z)$$

with

$$\Gamma_{\alpha;11}(z)\varphi = \left(s^{(\alpha)}_{\beta,k}(z)\delta_{kl} - G^{(\alpha)}_z(y^{(k)}, y^{(l)})(1-\delta_{kl})\right)\varphi \text{ for } \varphi \in \mathcal{H}_1,$$

where $s^{(\alpha)}_{\beta,k}(z) := \beta_k - \lim_{\eta \to 0} \left(G^{(\alpha)}_z(y^{(k)}, y^{(k)} + \eta) + \frac{1}{2\pi} \ln |\eta|\right)$ and $G^{(\alpha)}_z$ is the integral kernel of the operator $R_\alpha(z)$. In fact, this can be simplified as follows.

**Proposition 2.3** For any $z \in \rho(H_{\alpha,\beta})$ with $\text{Im} \, z > 0$ we have

$$R_{\alpha,\beta}(z) = R_\alpha(z) + R_{\alpha;L1}(z)D(z)^{-1}R_{\alpha;1L}(z).$$

**Proof.** Using the asymptotic behaviour of the Macdonald function we get

$$s^{(\alpha)}_{\beta,k}(z) = s_{\beta,k}(z) - (R_{10}(z)\Gamma_{00}(z)^{-1}R_{01}(z))_{kk}.$$  

This yields $\Gamma_{\alpha;11}(z) = D(z)$, and thus the claim of the proposition. $\blacksquare$
3 Spectral analysis

We begin the spectral analysis of $H_{\alpha,\beta}$ by localizing the essential spectrum. To this aim let us consider the auxiliary “line-only” operator $\tilde{H}_\alpha$ introduced above. Separating variables and using the fact that one-dimensional Laplace operator with a single point interaction of coupling constant $\alpha$ has just one isolated eigenvalue equal to $-\frac{1}{4}\alpha^2$ we find that $\sigma(\tilde{H}_\alpha) = \sigma_{ac}(\tilde{H}_\alpha) = [-\frac{1}{4}\alpha^2, \infty)$. The point interactions in $H_{\alpha,\beta}$ represent by Proposition 2.3 a finite-rank perturbation of the resolvent, hence the essential spectrum is preserved by Weyl’s theorem. Moreover, the explicit expression of the resolvent makes it possible to employ [19, Thm. XIII.19] to conclude that the singularly continuous spectrum of $H_{\alpha,\beta}$ is empty, i.e. that

$$\sigma_{ess}(H_{\alpha,\beta}) = \sigma_{ac}(H_{\alpha,\beta}) = [-\frac{1}{4}\alpha^2, \infty).$$

(3.1)

To demonstrate the existence of isolated points of the spectrum for $H_{\alpha,\beta}$ and to find the corresponding eigenvectors we employ the following equivalences,

$$z \in \sigma_d(H_{\alpha,\beta}) \iff 0 \in \sigma_d(\Gamma(z)) \iff \dim \ker(\Gamma(z)) = \dim \ker(H_{\alpha,\beta} - z),$$

(3.2)

$$H_{\alpha,\beta}\phi_z = z\phi_z \iff \phi_z = \sum_{i=0}^1 R_{Li}(z)\eta_i,z \quad \text{for} \quad z \in \sigma_{disc}(H_{\alpha,\beta}),$$

(3.3)

where $(\eta_{0,z}, \eta_{1,z}) \in \ker \Gamma(z)$. They are nothing else than a generalization of the Birman-Schwinger principle to the situation when the interaction in the Schrödinger operator in question is singular and supported by a zero-measure set; in the present form they follow from an abstract result of [18, Thm. 3.4]. Thus to investigate the discrete spectrum it suffices to study zeros of the operator-valued function $z \mapsto \Gamma(z)$. This will be the starting point for considerations in the rest of this section.

3.1 Discrete spectrum for one point interaction

We start with the simplest case when the interaction in $H_{\alpha,\beta}$ is supported by $\Sigma$ and at a single point $y$. In such a case, of course, we can choose $y = (0, a)$ with $a > 0$ without loss of generality. As indicated above the spectrum in $[-\frac{1}{4}\alpha^2, \infty)$ is purely absolutely continuous; our aim is to show that $H_{\alpha,\beta}$ has always exactly one isolated eigenvalue and to investigate its dependence.
on the distance \(a\) between \(y\) and \(\Sigma\). In particular, we will show that the eigenvalue behavior for large \(a\) basically depends on whether the number

\[
\epsilon_\beta = -4 e^{2(-2\pi\beta + \psi(1))},
\]

(3.4)

where \(-\psi(1) \approx 0.577\) is the Euler number, belongs to the absolutely continuous spectrum or not; recall that \(\epsilon_\beta\) is the only isolated eigenvalue of the point-interaction Hamiltonian \(H_\beta\) – cf. [2, Sec. I.5].

Since zeros \(\Gamma(z)\) determine eigenvalues of \(H_{\alpha,\beta}\), it is convenient to rewrite the operator \(\Gamma(z)\) in a more explicit form. It is straightforward to see that its part \(\Gamma^{00}(z)\) acts in the momentum representation as a simple multiplication, and therefore

\[
\Gamma^{00}(z)f(x) = \frac{1}{(2\pi)^{1/2}} \int_{\mathbb{R}} \left[\frac{1}{\alpha} - \frac{i}{2(z - p^2)^{1/2}}\right] \tilde{f}(p) e^{ipx} dp.
\]

Moreover, using the expression for the Green function of the one-dimensional Laplace operator,

\[
\frac{1}{2\pi} \int_{\mathbb{R}} \frac{e^{ipx}}{p^2 - z} dp = \frac{i}{2\sqrt{z}} e^{i\sqrt{z}|x|},
\]

(3.5)

we can express the “off-diagonal” operator components as

\[
(\Gamma_{01}(z)\phi)(x) = \nu_0^+(x)\phi, \quad \Gamma_{10}(z)f = \int_{\mathbb{R}} \nu_0^-(x)f(x) dx,
\]

(3.6)

for \(\phi \in \mathcal{H}_1\) and \(f \in \mathcal{H}_0\), respectively, where

\[
\nu_0^\pm(x) := \int_{\mathbb{R}} v_0(p) e^{\pm ipx} dp, \quad v_0(p) := \frac{i}{4\pi} \frac{e^{i(z-p^2)^{1/2}a}}{(z-p^2)^{1/2}}.
\]

(3.7)

While later we will consider analytic continuation of some of the resolvent “constituents”, with operators (3.6) it is sufficient to stay at the first sheet of \(z \mapsto (z - p^2)^{1/2}\), i.e. to suppose that \(\text{Im} (z - p^2)^{1/2} > 0\). In that case the functions \(\nu_0^\pm\) belong to \(\mathcal{H}_0\), and consequently, the “off-diagonal” operators, \(\Gamma_{ij}(z)\) with \(i \neq j\), are well defined.

To proceed further we make two observations. The first is the equivalence

\[
0 \in \sigma_d(\Gamma(z)) \iff 0 \in \sigma_d(D(z)),
\]

where \(D(z)\) is the reduced determinant of \(\Gamma(z)\) given by (2.4); this means that it suffices to investigate zeros of the map \(z \mapsto D(z)\). Secondly, as we know
that $H_{\alpha,\beta}$ is self-adjoint, we can restrict ourselves to $z = -\kappa^2$ with $\kappa > 0$. For convenience we introduce the abbreviations $\tilde{\Gamma}(\kappa) := \Gamma(-\kappa^2)$, $\tilde{D}(\kappa) = D(-\kappa^2)$, and the analogous symbols for other functions. By a straightforward computation using formulae (3.7), (3.6) one can check that $\tilde{D}(\kappa)$ is an operator of multiplication, $\tilde{D}(\kappa) \varphi = \tilde{d}(\kappa) \varphi$, by the number 
\[ \tilde{d}(\kappa) \equiv \tilde{s}_{\beta}(\kappa) := s_{\beta}(-\kappa^2) := \beta + \frac{1}{2\pi} \left[ \ln \frac{\kappa}{2} - \psi(1) \right]. \]
Consequently, roots of the equation
\[ \tilde{d}(\kappa) = 0 \quad \text{for} \quad \kappa \in (\frac{\alpha}{2}, \infty) \] (3.9)
determine through $z = -\kappa^2$ the discrete spectrum of $H_{\alpha,\beta}$.

Now we are ready to state a claim which characterizes the discrete spectrum of $H_{\alpha,\beta}$ in case of a single point perturbation.

**Theorem 3.1** For given $\alpha > 0$ and $\beta \in \mathbb{R}$ the operator $H_{\alpha,\beta}$ has exactly one isolated spectrum $-\kappa_a^2$ with the eigenvector which can be represented by
\[ \text{const} \int_{\mathbb{R}^2} \left( \frac{e^{-ip_2a}}{2\pi} + \frac{\alpha e^{-\left(p_1^2 + \kappa_a^2\right)^{1/2}}} {2(p_1^2 + \kappa_a^2)^{1/2} - \alpha} \right) \frac{e^{ipx}}{p^2 + \kappa_a^2} \, dp, \quad (3.10) \]
where we integrate with respect to $p = (p_1, p_2)$.

**Proof.** To check that there is a $\kappa_a$ satisfying (3.9) it suffices to investigate the behavior of $\tilde{d}_a$ at infinity and near the number $\frac{1}{2}\alpha$. Using the above definitions of $\tilde{s}_{\beta}$ and $\tilde{d}_{\alpha}$ it is easy to see that the function $\kappa \mapsto \tilde{d}_a(\kappa)$ is strictly increasing with the limits $\tilde{d}_a(\kappa) \to \pm \infty$ as $\kappa \to \infty$ and $\kappa \to \frac{1}{2}\alpha+$, respectively. Thus there is exactly one $\kappa_a \in \left(\frac{1}{2}\alpha, \infty\right)$ such that $\tilde{d}_a(\kappa_a) = 0$. Formula (3.10) can be obtained directly from (3.3). □
In this respect it is convenient to use the notation $H_{\alpha,\beta,a}$ for the operator in question. The answer is again contained in the behavior of the functions $\hat{s}_\beta(\cdot)$, and $\hat{\phi}_a(\cdot)$. Given $\kappa \in (\frac{1}{2}\alpha, \infty)$ we define the function $a \mapsto \hat{\phi}_\kappa(a) = \hat{\phi}_a(\kappa)$; using (3.8) it is easy to see that it is decreasing on the indicated interval. Combining this with the fact that $\hat{s}_\beta(\cdot)$ is increasing we come to the conclusion that the function $a \mapsto \kappa_a$ is decreasing on $(0, \infty)$. To determine its behavior at the endpoints if the interval let us notice that

$$\lim_{a \to \infty} \hat{\phi}_\kappa(a) = 0.$$ 

This limit in combination with the relation $\hat{s}_\beta(\sqrt{-\epsilon_\beta}) = 0$, where $\epsilon_\beta$ is the point-interaction eigenvalue given by (3.4), yields

$$\lim_{a \to \infty} \kappa_a = \sqrt{-\epsilon_\beta} \quad \text{if} \quad \sqrt{-\epsilon_\beta} \in (\alpha/2, \infty)$$

and

$$\lim_{a \to \infty} \kappa_a = \frac{\alpha}{2} \quad \text{if} \quad \sqrt{-\epsilon_\beta} \in (-\infty, \alpha/2].$$

Let us turn next to the behavior $a \mapsto \kappa_a$ for small $a$. To this aim we note that for a fixed $\kappa$ the expression

$$\tilde{\phi}_0(\kappa) := \frac{\alpha}{2\pi} \int_{\mathbb{R}} \frac{1}{(2(p^2 + \kappa^2)^{1/2} - \alpha)(p^2 + \kappa^2)^{1/2}} \, dp$$

provides an upper bound for $\hat{\phi}_a(\kappa)$. It straightforward to check that $\tilde{\phi}_0(\kappa) \to 0$ as $\kappa \to \infty$ and $\tilde{\phi}_0(\kappa) \to \infty$ as $\kappa \to \frac{1}{2}\alpha+$. It follows that there is a number $\kappa_0 \in (\frac{1}{2}\alpha, \infty)$ which is a solution of $\hat{s}_\beta(\kappa) - \tilde{\phi}_0(\kappa) = 0$ and provides an upper bound to the function $a \mapsto \kappa_a$. These considerations can be summarized as follows:

**Theorem 3.2** The eigenvalue $-\kappa_a^2$ of $H_{\alpha,\beta,a}$ is increasing as a function of the distance $a$. Moreover, we have

$$- \lim_{a \to \infty} \kappa_a^2 = \epsilon_\beta \quad \text{if} \quad \epsilon_\beta \in (-\infty, -\frac{1}{4}\alpha^2]$$

and

$$- \lim_{a \to \infty} \kappa_a^2 = -\frac{1}{4}\alpha^2 \quad \text{if} \quad \epsilon_\beta \in (-\frac{1}{4}\alpha^2, \infty).$$

On the other hand, $-\kappa_0^2$ is the best lower bound for $-\kappa_a^2$, i.e. we have

$$- \lim_{a \to 0} \kappa_a^2 = -\kappa_0^2.$$
3.2 A mirror-symmetric pair of point interactions

Generally speaking the case of \(n = 2\) can be treated within the discussion of the discrete spectrum of \(H_{\alpha,\beta}\) with \(n > 1\) presented in the next subsection. Here we single out the situation where the system has a mirror symmetry to illustrate that it can give rise to eigenvalues embedded in the continuous spectrum. To be specific, we assume that the interaction sites are located symmetrically with respect to the line \(\Sigma\), i.e. \(x_1 = (0, a), x_2 = (0, -a)\) with some \(a > 0\), and moreover, the coupling strengths are the same, \(\beta_1 = \beta_2 = \beta\).

As in the case \(n = 1\) the relation between the number \(-1/4 \alpha^2\) and the point-interaction eigenvalues will be important for spectral properties. Consider the system with the line component of the interaction removed which is described by the operator \(H_\beta\). It has \(\sigma_{ac}(H_\beta) = [0, \infty)\) and at least one and at most two eigenvalues. Let us denote them \(\mu_1, \mu_2\) and assume that \(\mu_1 < \mu_2\); if there exists only one eigenvalue we put \(\mu_2 := 0\). From the explicit resolvent formula \([2, \text{Sec. II.4}]\) it follows that \(\mu_i = -\kappa_i^2\), where \(\kappa_i\) are solutions of the equation

\[
\hat{s}_\beta(\kappa)^2 - K_0(2\kappa a)^2 = 0, \quad \kappa > 0,
\]

which implies the inequalities

\[
\mu_1 < \epsilon_\beta < \mu_2;
\]

they follow also from Dirichlet-Neumann bracketing \([19, \text{Sec. XIII.15}]\) and it is useful to note that the number \(\mu_1, \mu_2\) is the eigenvalue corresponding to the symmetric and antisymmetric eigenfunction of \(H_\beta\), respectively.

To find the isolated eigenvalue of \(H_{\alpha,\beta}\) we will employ the BS-principle expressed by (3.2). Proceeding similarly as in the previous section we show that the number \(-\tilde{\kappa}^2\) is an eigenvalue of \(H_{\alpha,\beta}\) iff \(\tilde{\kappa}\) is a solution of

\[
\tilde{d}(\kappa) = 0 \quad \text{for} \quad \kappa \in (\alpha/2, \infty),
\]

where the function \(\tilde{d}(\cdot)\) means the determinant of \(\tilde{D}(\cdot)\) being thus given by

\[
\tilde{d}(\kappa) = (\hat{s}_\beta(\kappa) + K_0(2\kappa a))(\hat{s}_\beta(\kappa) - K_0(2\kappa a) - 2\hat{\phi}_a(\kappa))
\]

and \(\tilde{d}(\kappa)\) is again given by (3.8), i.e.

\[
\hat{\phi}_a(\kappa) = \frac{\alpha}{4\pi} \int_{\mathbb{R}} \frac{e^{-2(p^2 + \kappa^2)^{1/2}a}}{(2(p^2 + \kappa^2)^{1/2} - \alpha)(p^2 + \kappa^2)^{1/2}} dp.
\]

Now we can describe the point spectrum of \(H_{\alpha,\beta}\) in the given situation.
**Theorem 3.3** \( H_{\alpha, \beta} \) has always at least one isolated eigenvalue. Moreover, 

(i) if \(-\frac{1}{4}\alpha^2 < \mu_2 < 0\), then \( H_{\alpha, \beta} \) has one isolated eigenvalue and one embedded eigenvalue which is equal to \( \mu_2 \),

(ii) on the other hand, if \( \mu_2 < -\frac{1}{4}\alpha^2 \), then \( H_{\alpha, \beta} \) has two isolated eigenvalues the larger of which is given by \( \mu_2 \).

**Proof.** Using the behavior of functions \( \tilde{s}_\beta, K_0, \tilde{\phi}_a \) at infinity and near the number \( \frac{1}{2}\alpha \) we can conclude that the equation

\[
\tilde{s}_\beta(\kappa) - K_0(2\kappa a) - 2\tilde{\phi}_a(\kappa) = 0
\]

coming from the second factor in the spectral condition has for any parameter values exactly one solution in \((\frac{1}{2}\alpha, \infty)\) which naturally solves also (3.12); this means that the operator \( H_{\alpha, \beta} \) has always at least one isolated eigenvalue. Moreover, if \( \mu_2 < -\frac{1}{4}\alpha^2 \) the equation (3.12) has one more solution given by the number \( \kappa_2 \); this completes the proof of (ii). Assume next \(-\frac{1}{4}\alpha^2 < \mu_2 < 0\). As we have already mentioned the number \( \mu_2 \) is the eigenvalue of \( H_\beta \) corresponding to eigenfunction \( \psi_{\mu_2} \) antisymmetric w.r.t. \( \Sigma \). It is easy to see that \( \psi_{\mu_2} \in D(H_{\alpha, \beta}) \) and both the boundary functions \( \Xi_\Sigma(\psi_{\mu_2}), \Omega_\Sigma(\psi_{\mu_2}) \) vanish. This implies \( H_{\alpha, \beta}\psi_{\mu_2} = H_\beta\psi_{\mu_2} \), in other words that \( \psi_{\mu_2} \) is at the same time an eigenvector of \( H_{\alpha, \beta} \) corresponding to \( \mu_2 \).

**Remark 3.4** Let us note here that the condition

\[
\epsilon_\beta > -\frac{1}{4}\alpha^2
\]

is sufficient for \( \mu_2 > -\frac{1}{4}\alpha^2 \) in view of (3.11), while the converse statement is not true in general. It may happen when the distance \( a \) is sufficiently small that even if \( \epsilon_\beta \) is below the threshold of the essential spectrum, the number \( \mu_2 \) would satisfy \( \mu_2 > -\frac{1}{4}\alpha^2 \) so according to Theorem 3.3 it will appear in spectrum of \( H_{\alpha, \beta} \) as an embedded eigenvalue.

### 3.3 Finitely many point interactions

Let us finally turn to analysis of the discrete spectrum in the general case with finitely many points of interaction and coupling constants determined by components of the vector \( \beta = (\beta_1, \ldots, \beta_n) \). We assume that the perturbations are located at \( y^{(i)} = (l_i, a_i) \), where \( l_i \in \mathbb{R}, a_i \in \mathbb{R}\setminus\{0\} \), and denote by

\[
d_{ij} := |y^{(i)} - y^{(j)}|
\]
the distances between them. Our strategy will be similar as before, namely, to recover the discrete spectrum of $H_{\alpha,\beta}$ we will employ the equivalence (3.2) which allows us to describe eigenvalues of $H_{\alpha,\beta}$ in the terms of zeros of $z \mapsto \Gamma(z)$. This in turn can be reduced to the problem of finding zeros of the $n \times n$ matrix $D(z) := \Gamma_{11}(z) - \Gamma_{10}(z)\Gamma_{00}(z)^{-1}\Gamma_{01}(z)$: $\mathcal{H}_1 \to \mathcal{H}_1$ for $z$ negative. To proceed further we introduce the notation $\Gamma_{j;i}$ for the $j$-th component of $\Gamma_{10}$ and $\Gamma_{i;j}$ for the corresponding matrix element of $\Gamma_{11}$. We also introduce the following auxiliary functions of $z \in \mathbb{C} \setminus \left[-\frac{1}{4}\alpha^2, \infty\right)$,

$$\Theta^j_{i_1} := \Gamma_{j,0}\Gamma_{0i_1},$$

$$A^j_{i_2,\ldots,i_k} := \begin{cases} 
\Gamma_{1;i_2}\ldots\Gamma_{j-1;i_2}\Gamma_{j+1;i_j}\ldots\Gamma_{k;i_k} & \text{if } j > 1, \\
\Gamma_{2;i_2}\ldots\Gamma_{k;i_k} & \text{if } j = 1.
\end{cases}$$

A straightforward computation shows that the determinant of $D(\cdot)$ is given by the function $d(\cdot)$ with the values

$$d(z) = \sum_{\pi \in \mathcal{P}_n} \text{sgn} \pi \left( \sum_{j=1}^{n} (-1)^j S^j_{p_1,\ldots,p_n} + \Gamma_{1,p_1}\ldots\Gamma_{n,p_n} \right)(z), \quad (3.15)$$

where $S^j_{p_1,\ldots,p_n} := \Theta^j_{p_1}A^j_{p_2,\ldots,p_n}$, $\mathcal{P}_n$ is the permutation group of $(1,\ldots,n)$, and $\pi = (p_1,\ldots,p_n)$ is an element of $\mathcal{P}_n$. Since we are interested in the negative part of spectrum we put $\tilde{d}(\kappa) = d(-\kappa^2)$ and same convention will be kept for the other expressions. According to the above general discussion the eigenvalues of $H_{\alpha,\beta}$ are determined by solution of the equation

$$\tilde{d}(\kappa) = 0 \quad \text{for} \quad \kappa \in (\alpha/2, \infty). \quad (3.16)$$

To concretize the function $\tilde{d}(\cdot)$ we need more information about the functions involved in the definition of $D(\cdot)$. We have

$$\tilde{\Theta}^j_k(\kappa) = \frac{\alpha}{4\pi} \int_{\mathbb{R}} \frac{e^{-(p^2 + \kappa^2)^{1/2}(|a_i| + |a_j|)}}{(2(p^2 + \kappa^2)^{1/2} - \alpha)(p^2 + \kappa^2)^{1/2}} e^{ip(l_j - l_k)} \, dp \quad (3.17)$$

and

$$\tilde{\Gamma}_{j;k}(\kappa) = -\frac{1}{2\pi} K_0(d_{jk}\kappa) \quad \text{for } j \neq k; \quad (3.18)$$

recall that the diagonal elements for $j \geq 1$ are given by the numbers $\tilde{\Gamma}_{j;j}(\kappa) = \hat{s}_{\beta_j}(\kappa)$. After these preliminaries we ready to prove the following theorem.
Theorem 3.5 Let $\beta = (\beta_1, \ldots, \beta_n)$, where $\beta_i \in \mathbb{R}$ and $\alpha > 0$. The operator $H_{\alpha,\beta}$ has at least one isolated eigenvalue and at most $n$ of them; they are determined by solutions of the equation (3.16). In particular, if all the numbers $-\beta_i$ are sufficiently large then $H_{\alpha,\beta}$ has exactly $n$ eigenvalues.

Proof. Let us consider again the operator $\hat{H}_\alpha$ defined in sec. 2.1. Since it is symmetric with deficiency indices $(n, n)$ and $\hat{H}_\alpha \geq -\frac{1}{4} \alpha^2$, there are at most $n$ eigenvalues of $H_{\alpha,\beta}$ – cf. [20, Sec. 8.4]. The remaining part of the proof will be divided into four steps.

1st step: We will show that if all the numbers $\beta_i$ are sufficiently large then the equation (3.16) has at least one solution. To this aim we shall investigate the behaviour of $\check{d}(\cdot)$ at infinity and near the number $\frac{1}{2} \alpha$. It is easy to see that for large values of the argument $\kappa$ the behaviour of the function $\check{d}$ is determined by the term $\prod_{i=1}^{n} \check{\Gamma}_{i,i} = \prod_{i=1}^{n} \check{s}_{\beta_i}$; this implies

$$\check{d}(\kappa) \to \infty \quad \text{as} \quad \kappa \to \infty.$$ (3.19)

On the other hand, the function $\check{d}$ has a singularity at $\frac{1}{2} \alpha$ induced by $\check{\Theta}_j^i$. This fact allows us to conclude that if all the numbers $\beta_i$ are sufficiently large then the behaviour of $\check{d}(\kappa)$ near $\frac{1}{2} \alpha$ is dominated by the components of $-S^j_{j,1,2,\ldots,j-1,j+1,\ldots,n}$ which look like $-\check{\Theta}_j^i \beta_1 \cdots \beta_{j-1} \beta_{j+1} \cdots \beta_n$. Since they are all negative under our assumption, we arrive at

$$\check{d}(\kappa) \to -\infty \quad \text{as} \quad \kappa \to \frac{1}{2} \alpha.$$ (3.19)

Combining this with (3.19) we demonstrate the existence of at least one solution of (3.16) if the coupling constants $\beta_i$ are sufficiently large.

2 step: Notice further that the functions $\check{\Gamma}_{i,i} = \check{s}_{\beta_i}$ are increasing with respect to each parameter $\beta_i$ while the other matrix elements of $\check{\Gamma}$ are independent of all the $\beta_i$. Combining this with the minimax principle and the results obtained in the previous step we find that for all $\beta_1, \ldots, \beta_n$ there exists at least one solution of (3.16), and consequently, an eigenvalue of $H_{\alpha,\beta}$.

3 step: Let $\tilde{\kappa}$ be a solution to (3.16). From (3.17), (3.18) in combination with the explicit expression for $\check{s}_{\beta_i}$ one finds that if all the coupling constants $\beta_i \to -\infty$ then $\tilde{\kappa}$ tends to infinity or to the number $\frac{1}{2} \alpha$. However, the latter is excluded by the monotonicity proved in the previous step. Thus we obtain

$$\tilde{\kappa} \to \infty \quad \text{as} \quad \beta_i \to -\infty \quad \text{for} \quad i = 1, \ldots, n.$$
4 step: Using the explicit formulae for operators $\Gamma_{i,j}$ one check that operator $\Gamma(\kappa)$ approaches $\hat{S}(\kappa)$ in the norm operator sense as $\kappa \to \infty$, where $\hat{S}(\kappa)$ is the operator-valued diagonal matrix given by

$$
\begin{align*}
\hat{S}_{00}(\kappa) &= 0, \\
\hat{S}_{11}(\kappa) &= \left[\hat{s}_{\beta_k}(\kappa)\delta_{kl}\right]_{k,l=1}^n, \\
\hat{S}_{ij}(\kappa) &= 0 \quad \text{for } i, j = 0, 1 \quad \text{and} \quad i \neq j.
\end{align*}
$$

Since there exist $n$ solutions of the operator equation $\hat{S}(\kappa) = 0$ we arrive at the final conclusion that for $-\beta_i$ sufficiently large the operator $H_{\alpha,\beta}$ has the “full number” $n$ of isolated eigenvalues.

4 Resonances

Determining the spectrum as a set does not exhaust interesting properties of the present model; now we turn to features “hidden” in the continuous component (3.1). We will concentrate at the negative part of this interval, where in the absence of point perturbations we have a simple one-dimensional transport: the wavefunctions factorize into the transverse factor which is the eigenfunction of the one-dimensional point interaction, and the longitudinal one which a wave packet which moves and spreads in the usual way. If we add now point perturbation(s) the transport may be affected by tunneling between the line and these singular “potential wells”, at least if such a process is energetically allowed; our goal stated in the introduction is to show existence of “tunneling” resonances and to find their properties. For the sake of simplicity we shall consider mostly (with the exception of Sec. 4.2 below) the case when the Hamiltonian $H_{\alpha,\beta}$ has a single point perturbation.

Following the standard ideology, to find resonances we have to construct the analytical continuation of $z \mapsto R_{\alpha,\beta}(z)$ to the second sheet across the cut corresponding to the continuous spectrum and to find poles of this continuation. Our main insight is that the constituents of the operator at the right-hand side of (2.6) can be separately continued analytically, and moreover as we remarked above, for the factors (3.6) in fact no continuation is needed, i.e. we may suppose that $\text{Im} (z - p^2)^{1/2} > 0$. Thus we have to deal only with the middle factor in the interaction term of (2.6), in other words, we can extend the Birman-Schwinger principle to the complex region and to look for zeros in the analytic continuation of $D(\cdot)$. Taking into account
the structure of the auxiliary space $\mathcal{H}_0 \oplus \mathcal{H}_1$ we get in this way a problem reminiscent of the Friedrichs model – cf. [14], or [6, Sec. 3.2] for a review.

4.1 Resonance for $H_{\alpha,\beta}$ with a single point interaction

The Friedrichs model analogy suggests to treat our problem perturbatively assuming that in the “decoupled” case which corresponds here to the limit $a \to \infty$ we have the point interaction eigenvalue $\epsilon_\beta$ embedded in the continuous spectrum. Following the above sketched program we notice first that by formulae (3.5), (3.6), and (3.7) the operator-valued function $z \mapsto D(z)$, $z \in \mathbb{C} \setminus [-\frac{1}{4} \alpha, \infty)$ is now one-dimensional, i.e. a multiplication by the function

$$d_a(z) = s_\beta(z) - \phi_a(z), \quad \text{where} \quad \phi_a(z) := \int_0^\infty \frac{\mu(z, t)}{t - z - \frac{1}{4} \alpha^2} \, dt,$$

and

$$\mu(z, t) := \frac{i \alpha}{2^5 \pi} \frac{(\alpha - 2i(z - t)^{1/2}) e^{2i(z-t)^{1/2}a}}{t^{1/2}(z - t)^{1/2}}.$$

Since the numbers 0 and $-\frac{1}{4} \alpha^2$ are branching points of the function $d_a$ we will construct its continuation across the interval $(-\frac{1}{4} \alpha^2, 0)$ to a subset $\Omega_-$ of the lower half plane. Let us first consider the second component $\phi_a$. To find its analytical continuation to the second sheet for $\lambda \in (-\frac{1}{4} \alpha^2, 0)$ we define

$$\mu^0(\lambda, t) := \lim_{\varepsilon \to 0^+} \mu(\lambda + i \varepsilon, t) \quad \text{and} \quad I(\lambda) := \mathcal{P} \int_0^\infty \frac{\mu^0(\lambda, t)}{t - \lambda - \frac{1}{4} \alpha^2} \, dt$$

with the integral understood in the principal-value sense. We also denote

$$g_{\alpha, a}(z) := \frac{i \alpha}{8} \frac{e^{-\alpha a}}{(z + \frac{1}{4} \alpha^2)^{1/2}} \quad \text{for} \quad z \in \Omega_- \cup (-\frac{1}{4} \alpha^2, 0);$$

then we are ready to formulate a lemma describing the analytic continuation of $\phi_a$; we postpone its proof to the appendix.

**Lemma 4.1** The function $z \mapsto \phi_a(z)$ defined in (4.1) can be continued analytically across $(-\frac{1}{4} \alpha^2, 0)$ to a region $\Omega_-$ of the second sheet as follows,

$$\phi_a^0(\lambda) = I(\lambda) + g_{\alpha, a}(\lambda) \quad \text{for} \quad \lambda \in (-\frac{1}{4} \alpha^2, 0),$$

$$\phi_a^-(z) = -\int_0^\infty \frac{\mu(z, t)}{t - z - \frac{1}{4} \alpha^2} \, dt - 2g_{\alpha, a}(z) \quad \text{for} \quad z \in \Omega_-, \ \text{Im} z < 0.$$
Notice that apart of fixing a part of its boundary, we have imposed no restrictions on the shape of $\Omega_-$. The lemma allows us to construct the sought analytic continuation of $d_a(\cdot)$ across the indicated segment of the real axis because the other component has no cut there. It is given by the function $\eta_a : M \mapsto \mathbb{C}$, where $M := \{z : \text{Im } z > 0\} \cup (-\frac{1}{4}\alpha^2, 0) \cup \Omega_-$, acting as

$$
\eta_a(z) = s_\beta(z) - \phi^l(z)(z),
$$

where $l(z) = \pm$ if $\pm \text{Im } z > 0$ and $l(z) = 0$ if $z \in (-\frac{1}{4}\alpha^2, 0)$, respectively; we also put $\phi^+_a \equiv \phi$. The problem at hand is now to show that $\eta_a(\cdot)$ has a second-sheet zero, i.e. $\eta_a(z) = 0$ for some $z \in \Omega_-$. To proceed further it is convenient to put $\varsigma_\beta(z) := \sqrt{-\epsilon_\beta}$, and since we are interested here primarily in large distances $a$, to make the following reparametrization,

$$
b := e^{-a \varsigma_\beta} \quad \text{and} \quad \tilde{\eta}(b, z) := \eta_a(z) : [0, \infty) \times M \mapsto \mathbb{C};
$$

we look then for zeros of the function $\tilde{\eta}$ for small values of $b$. With this notation we have

$$
\mu^0(\lambda, t) = \frac{\alpha}{2b^3 \pi} \frac{(a + 2(t - \lambda)^{1/2}) b^{2(t - \lambda)^{1/2}/\varsigma_\beta}}{t^{1/2}(t - \lambda)^{1/2}}, \quad g_{a,a}(b)(\lambda) = \frac{i\alpha}{8} \frac{b^{\alpha/\varsigma_\beta}}{(\lambda + \frac{1}{4}\alpha^2)^{1/2}},
$$

for $\lambda \in (-\frac{1}{4}\alpha^2, 0)$, where $a(b) := -\frac{1}{\varsigma_\beta} \ln b$, and similarly for the other constituents of $\tilde{\eta}$. This yields our main result in this section.

**Theorem 4.2** Assume that $\epsilon_\beta > -\frac{1}{4}\alpha^2$. For any $b$ small enough the function $\tilde{\eta}(\cdot, \cdot)$ has a zero at a point $z(b) \in \Omega_-$ with the real and imaginary part, $z(b) = \mu(b) + i\nu(b)$, $\nu(b) < 0$, which in the limit $b \to 0$, i.e. $a \to \infty$, behave in the following way,

$$
\mu(b) = \epsilon_\beta + \mathcal{O}(b), \quad \nu(b) = \mathcal{O}(b).
$$

**Proof.** By assumption we have $\varsigma_\beta \in (0, \frac{1}{2}\alpha)$. Using formulae (4.2) together with the similar expressions of $\mu(z, t)$ and $g_{a,a}(z)$ in terms of $b$ one can check that for a fixed $b \in [0, \infty)$ the function $\tilde{\eta}(b, \cdot)$ is analytic in $M$, while with respect to both variables $\tilde{\eta}$ is just of the $C^1$ class in a neighbourhood of the point $(0, \epsilon_\beta)$. Moreover, it is easy to see that for $\lambda$ close to $\epsilon_\beta$ the function $\phi^0_{a,b}(\cdot)$ can majorized by the expression $C b^M$, where $C, M$ are constants and $M > 1$. This implies $\tilde{\eta}(0, \epsilon_\beta) = 0$ and $\partial_z \tilde{\eta}(0, \epsilon_\beta) \neq 0$. Thus by the
implicit function theorem there exists a neighbourhood $U_0$ of zero and a unique function $z(b) : U_0 \rightarrow \mathbb{C}$ such that $\tilde{\eta}(b, z(b)) = 0$ holds for all $b \in U_0$. Since $H_{\alpha, \beta}$ is self-adjoint, $\nu(b)$ cannot be positive, while $z(b) \in (-\frac{1}{4}\alpha^2, 0)$ for $b \neq 0$ can be excluded by inspecting the explicit form of $\tilde{\eta}$. Finally, by the smoothness properties of $\tilde{\eta}$ both the real and imaginary part of $z(b)$ are of the $C^1$ class which yields the behaviour (4.3).

**Remark 4.3** The above theorem confirms what one expects about the behaviour of the pole using the heuristic idea about tunneling between the point and the line, namely that the resonance width $\Gamma(b) = 2\nu(b)$ is exponentially small for $a$ large. It also natural to ask how the resonance pole behaves for a general $a$, in particular, whether it may disappear for $a \rightarrow 0$. Using the explicit formulae of Lemma 4.1 one can check the following convergence,

$$|\phi_a^-(z)| \rightarrow 0 \quad \text{as} \quad \text{Im } z \rightarrow -\infty,$$

uniformly with respect to $a$. On the other hand, it is easy to see that

$$|s_{\beta}(z)| \rightarrow \infty \quad \text{as} \quad \text{Im } z \rightarrow -\infty.$$

This means that the imaginary part of $z(a)$ which represents the solution of $s_{\beta}(z) - \phi_a^-(z) = 0$ is a function uniformly bounded with respect to $a$; thus the resonance pole survives the limit $a \rightarrow 0$.

### 4.2 Resonances induced by broken symmetry

If there is more than one point interaction our model may exhibit another sort of resonances coming from broken symmetry. We restrict ourselves to the simplest case $n = 2$. As have seen in Sec. 3.2 the system with two points interactions placed symmetrically with respect to the line $\Sigma$ and with equal coupling constants $\beta_1, \beta_2$ may have an embedded eigenvalue for appropriate parameter values. If we break the symmetry the corresponding resolvent pole will leave the continuous spectrum and shift to the second sheet of the analytically continued resolvent giving rise to a resonance. Of course, there are various ways how the mirror symmetry can be broken.

#### 4.2.1 Symmetry broken by a coupling constant

Suppose first that the geometrical symmetry remains preserved, i.e. the point interactions are located at $x_1 = (0, a), x_2 = (0, -a)$ with $a > 0$. The
symmetry breaking will be due to unequal coupling parameters: assume that
the latter are $\beta \equiv \beta_1$ and $\beta_2 = \beta + q$, where $q \in \mathbb{R} \setminus \{0\}$. To get a nontrivial
result, similarly as in Sec. 3.2 we suppose that $0 > \mu_2 > -\frac{1}{4} \alpha^2$.

To find the pole position we proceed as in Sec. 3.2; we write the corre-
sponding $2 \times 2$ reduced determinant, construct its analytical continuation and
look for its zeros at the second sheet. This leads to the following equation,

$$\eta_q(z) = 0, \quad (4.4)$$

where

$$\eta_q(z) := s_\beta(z)(s_\beta(z) + q) - K_0(2a \sqrt{-z})^2 - (2s_\beta(z) + q)\phi_0^{(z)}(z) - 2K_0(2a \sqrt{-z})\phi_0^{(z)}(z)$$

and $\phi_0^{(z)}(\cdot)$ has been defined in Lemma 4.1. Our aim is to show that the
function $\tilde{\eta}(q, z) : \mathbb{R} \setminus \{0\} \times M \to \mathbb{C}$ defined by $\tilde{\eta}(q, z) = \eta_q(z)$ has a zero in
the lower halfplane; the set $M$ is determined here as before, namely $M = \{z : \text{Im } z > 0\} \cup \Omega_-$. Moreover, we put

$$\tilde{g}(\lambda) := -ig_{\alpha,a}(\lambda) = \frac{\alpha}{8} \frac{e^{-\alpha a}}{(\lambda + \frac{1}{4} \alpha^2)^{1/2}}$$

and use again $\kappa_2 := \sqrt{-\mu_2}$. It is also convenient to denote

$$\vartheta \equiv \vartheta(\kappa_2) := \frac{\kappa_2}{s_\beta'(\kappa_2) + 2aK_0'(2ak_2)},$$

where the primes stand for the derivatives of the corresponding functions;
with this notations we can make the following claim.

**Theorem 4.4** Suppose that $\mu_2 \in (-\frac{1}{4} \alpha^2, 0)$, then for all nonzero $q$ small
enough the equation $(4.4)$ has a solution $z(q) \in \Omega_-$ with the real and imagi-
nary part, $z(q) = \hat{\mu}(q) + i\hat{\nu}(q)$, which are real-analytic functions of $q$ having
the following expansions,

$$\hat{\mu}(q) = \mu_2 + \vartheta(\kappa_2)q + O(q^2),$$

$$\hat{\nu}(q) = -\vartheta(\kappa_2)\frac{\tilde{g}(\mu_2)}{2|s_\beta'(\kappa_2) - \phi_0'(\mu_2)|^2}q^2 + O(q^3).$$

**Proof.** As in Theorem 4.2 we rely on the implicit function theorem, but $\tilde{\eta}$
is now jointly analytic, so is $z_2$. Since $s_\beta'(\kappa_2) + 2aK_0''(2ak_2) > 0$ the leading
term of $\hat{\nu}(q)$ is negative. ■
Remark 4.5 The solution described in the theorem is not unique, another one comes from the symmetric eigenfunction of the corresponding Hamiltonian. This can be either a perturbed eigenvalue if $\mu_1$ is isolated, or another resonance if $\mu_1$ is also embedded; in the threshold case, $\mu_1 = -\frac{1}{4}\alpha^2$, the behaviour depends on the sign of $q$.

4.2.2 Symmetry broken by distance from the line

Assume now on the contrary that the coupling strengths are the same, $\beta \equiv \beta_1 = \beta_2$, while one of the point is shifted in the perpendicular direction, $x_1 = (0, a)$ and $x_2 = (0, -a - \delta)$, where $\delta \in \mathbb{R}$. Now the equation determining the resolvent pole acquires the form

$$
\tilde{\eta}(\delta, z) := s_\beta(z)^2 - K_0((2a + \delta)\sqrt{-z})^2 - s_\beta(z)(\phi^{(l)}_{\alpha+\delta}(z) + \phi^{(l)}_\alpha(z))
- 2K_0((2a + \delta)\sqrt{-z})\phi^{(l)}_{\alpha+\delta/2}(z) = 0.
$$

We keep notation $\kappa_2 = \sqrt{-\mu_2}$ and put also

$$
f(\delta, \kappa) = \tilde{\eta}(\delta, \sqrt{-\kappa^2}).
$$

Theorem 4.6 Assume $0 > \mu_2 > -\frac{1}{4}\alpha^2$. For all nonzero and sufficiently small $\delta$ the function $\tilde{\eta}(\delta, z)$ has a zero at a point $z(\delta) \in \Omega_-$ with the real and imaginary part $z(\delta) = \nu(\delta) + i\iota(\delta)$ admitting the asymptotics

$$
\nu(\delta) = \mu_2 - 2\kappa_2\kappa'_2\delta + O(\delta^2), \quad \iota(\delta) = -\kappa_2\kappa''_2\delta^2 + O(\delta^3),
$$

(4.5)

where

$$
\kappa'_2 = -\frac{2aK'_0(2a\kappa_2)}{s_\beta'(\kappa_2) + 2aK'_0(2a\kappa_2)}, \quad \kappa''_2 = \frac{2f_{\kappa,\kappa}\delta + f_{\kappa,\kappa}\kappa'_2 - f_{\kappa,\delta}\kappa' \kappa'_2}{f^2_{\kappa}}
$$

and $f, f_{ij}$ are appropriated derivatives at the point $\{\delta, \kappa\} = \{0, \kappa_2\}$. Moreover, we have $\iota(\delta) < 0$.

Proof. Similarly to Theorem 4.2 the argument is straightforward being based on the implicit function theorem, hence we restrict ourselves to commenting on the inequality $\iota(\delta) < 0$. Let $z(\delta) \in (-\frac{1}{4}\alpha^2, 0)$. Without losing generality we can assume $\delta > 0$ because the leading term of $\iota(\delta)$ is quadratic in $\delta$, then $
\kappa_2(\delta) = \sqrt{-\nu(\delta)} = \kappa_2 + \kappa'_2\delta + O(\delta^2) > \kappa_2$. It is easy to see that the first and the second component of $\tilde{\eta}(\delta, z(\delta))$ are real if the number $z(\delta)$ is real;
furthermore, using the explicit form for $\phi^{l(z)}_a$ and properties of the exponential function one can check that

$$\text{Im} f(\delta, \kappa_2(\delta)) < -2 \text{Im} \left( g_{a,a+\delta/2}(z(\delta)) (\delta_\beta(\kappa_2(\delta)) + K_0((2a + \delta)\kappa_2(\delta))) \right).$$

Since we have $\delta_\beta(\kappa_2(\delta)) + K_0((2a + \delta)\kappa_2(\delta)) > 0$ the imaginary part of $f(\delta, \kappa_2(\delta))$ is strictly negative. Consequently, $z(\delta)$ can not be a real number, and the possibility $\text{Im} z(\delta) > 0$ is excluded by general spectral properties of self-adjoint operators.

4.3 Scattering

While resonances in the analytically continued resolvent typically coincide with poles of the continued scattering matrix, this property does not hold automatically and has to be checked for each particular system separately. Our next goal is to illustrate it in the present setting, again in the simplest case with a single point interaction localized at the point $y$. To this aim we have thus to construct the $S$ matrix for the pair $(H_{\alpha,\beta}, \tilde{H}_\alpha)$. Since the operator $H_{\alpha,\beta}$ represents a rank-one perturbation of $\tilde{H}_\alpha$, the existence and completeness of the corresponding wave operators follows immediately from the Kuroda-Birman theorem. Consequently, the $S$ matrix is unitary; our aim is to find the on-shell $S$-matrix in the interval $(-\frac{1}{4}a^2, 0)$, i.e. the corresponding transmission and reflection amplitudes.

4.3.1 The on-shell $S$ matrix

Using the notation introduced above and Proposition 2.3 we can write the resolvent for $\text{Im} z > 0$ as

$$R_{\alpha,\beta}(z) = R_\alpha(z) + \eta_a(z)^{-1} (\cdot, v_z) v_z,$$

where the rank-one part in the last term is given by $v_z := R_{\alpha;L1}(z)$. We set $z = \lambda + i\varepsilon$ and apply the operator $R_{\alpha,\beta}(\lambda + i\varepsilon)$ to

$$\omega_{\lambda+i\varepsilon}(x) := e^{i(\lambda+i\varepsilon+\alpha^2/4)^{1/2}x_1} e^{-\alpha|x_2|/2},$$

then we take the limit $\varepsilon \to 0+$ in the sense of distributions. A straightforward if tedious calculation shows that $H_{\alpha,\beta}$ has a generalized eigenfunction which
for large $|x_1|$ behaves as

$$
\psi_\lambda(x) \approx e^{i(\lambda+\alpha^2/4)x_1} e^{-\alpha|x_2|/2}
$$

\[ \quad + \frac{i}{8} \alpha \eta_0(\lambda)^{-1} \frac{e^{-\alpha a}}{(\lambda + \frac{1}{4}\alpha^2)^{1/2}} e^{i(\lambda+\alpha^2/4)|x_1|} e^{-\alpha|x_2|/2} \quad (4.7) \]

for each $\lambda \in (-\frac{1}{4}\alpha^2, 0)$. To be more specific about derivation of the above formula, one has to use again (2.3) and to rely on considerations analogous to those in the proof of Lemma 4.1 to arrive at

$$
v_\lambda = \lim_{\varepsilon \to 0} v_{\lambda+i\varepsilon} = R_{L1}(\lambda) + S(\lambda), \quad (4.8)
$$

where

$$
S(\lambda) = I_\lambda(x_1, x_2) + \frac{i}{8} \alpha e^{-\alpha(a+|x_2|)/2} e^{i(\lambda+\alpha^2/4)|x_1|} e^{i|x_2|(t-\lambda)^{1/2}} e^{it^{1/2}x_1} dt;
$$

and

$$
I_\lambda(x_1, x_2) := \mathcal{P} \int_0^\infty \frac{\mu^0(\lambda, t)}{t - \lambda - \frac{1}{4}\alpha^2} e^{-|x_2|(t-\lambda)^{1/2}} e^{it^{1/2}x_1} dt;
$$

here $\mu^0(\lambda, t)$ is defined in Sec. 4.1. Furthermore, note that the first component of (4.8) as well as $I_\lambda(x_1, x_2)$ vanish for $|x_1| \to \infty$, and at the same time

$$
\lim_{\varepsilon \to 0} (\omega_{\lambda+i\varepsilon}, v_{\lambda+i\varepsilon}) = e^{-\alpha a/2}.
$$

In view of the results of Sec. 4.1 and (4.6) this yields formula (4.7) which, in turn, gives the sought quantities (see also Appendix B).

**Proposition 4.7** The reflection and transmission amplitudes are given by

$$
\mathcal{R}(\lambda) = T(\lambda) - 1 = \frac{i}{8} \alpha \eta_0(\lambda)^{-1} \frac{e^{-\alpha a}}{(\lambda + \frac{1}{4}\alpha^2)^{1/2}};
$$

they have the same pole in the analytical continuation to the region $\Omega_-$ as the continued resolvent.

### 4.4 Unstable state decay

It is also useful to look at the resonance problem from the complementary point of view and to investigate the decay of an unstable state associated with the resonance. Let us consider again the simplest case $n = 1$. The previous
results tell us that if the “unperturbed” eigenvalue $\epsilon_\beta$ of $H_\beta$ is embedded in $\left(-\frac{1}{4}\alpha^2, 0\right)$ and $a$ is large enough then the corresponding resonance state has a long half-life. In analogy with the Friedrichs model [4] one might expect that in the weak-coupling case, which corresponds to a large distance $a$ here, the resonance state would be similar up to normalization to the eigenvector $\xi_0 := K_0(\sqrt{-\epsilon_\beta} \cdot)$ of $H_\beta$ corresponding to $\epsilon_\beta$, with the decay law being dominated by the exponential term.

However, the present model is different in one important aspect. In a typical decay problem the decaying state belongs to the absolutely continuous subspace of the Hamiltonian and thus the decay law tends to zero as $t \to \infty$ by Riemann-Lebesgue lemma [6]. Here we know from Sec. 3.1 that $H_{\alpha,\beta}$ has always an isolated eigenvalue, and it is easy to see that the latter is not orthogonal to $\psi_{\alpha,\beta,a}$ for any $a$; it is sufficient to realize that both functions are positive, up to a possible phase factor. Consequently, the decay law $|(\xi_0, U(t)\xi_0)|^2||\xi_0||^{-2}$ has always a nonzero limit as $t \to \infty$ which is equal to the squared norm of the projection of $\xi_0||\xi_0||^{-1}$ on the eigensubspace given by $\psi_{\alpha,\beta,a}$. On the other hand, this fact does not exclude that the decay is dominated by the natural exponential term as $a \to \infty$; it may happen that the nonzero limit, which certainly depends on $a$, is hidden in the non-exponential error term. This question requires a longer discussion and we postpone it to a subsequent publication.

5 Three dimensions: a plane and points

In analogy with the two-dimensional case investigated in the previous sections we are going to discuss now briefly generalized Schrödinger operators in $L^2(\mathbb{R}^3)$ corresponding to the formal expression

$$-\Delta - \alpha \delta(x - \Lambda) + \sum_{i=1}^{n} \tilde{\beta}_i \delta(x - y^{(i)}) , \quad (5.1)$$

where $\alpha > 0$, $\beta_i \in \mathbb{R}$ and $\Lambda := \{(x_1, 0); \ x_1 \in \mathbb{R}^2\}$ is a plane, with $y^{(i)} \in \mathbb{R}^3 \setminus \Lambda$; for the point set we will keep the same notation, $\Pi := \{y^{(i)}\}_{i=1}^{n}$.

5.1 Definition of Hamiltonian

To write down appropriate boundary conditions let us consider functions $f \in W^{2,2}_{\text{loc}}(\mathbb{R}^3 \setminus (\Lambda \cup \Pi)) \cap L^2(\mathbb{R}^3)$ which are continuous at $\Lambda$. For any such
function we put \( f \mid_{C_{\rho,i}} \) as its restriction to the points \( x \in C_{\rho,i} \equiv C_{\rho}(y_i) := \{ q \in \mathbb{R}^3 : |q - y(i)| = \rho \} \). In analogy with the two-dimensional case we set

\[
\Xi_i(f) := \lim_{\rho \to 0} \frac{1}{\rho} f \mid_{C_{\rho,i}}, \quad \Omega_i(f) := \lim_{\rho \to 0} [ f \mid_{C_{\rho,i}} - \Xi_i(f) \rho ]
\]

for \( i = 1, \ldots, n \), and

\[
\Xi_\Lambda(f)(x_1) := \partial_{x_2} f(x_1, 0^+) - \partial_{x_2} f(x_1, 0^-), \quad \Omega_\Lambda(f)(x_1) := f(x_1, 0),
\]

and we assume that the above limits are finite and satisfy the relations

\[
\Xi_i(f) = 4\pi\beta_i \Omega_i(f), \quad \Xi_\Lambda(f)(x_1) = -\alpha \Omega_\Lambda(f)(x_1). \tag{5.2}
\]

Then we define \( H_{\alpha,\beta} \) as the Laplace operator with the boundary conditions given now by (5.2); it is straightforward to check that it is self-adjoint on its natural domain.

5.2 Resolvent of \( H_{\alpha,\beta} \)

In the three-dimensional case the free resolvent \( R(z) \) with \( z \in \rho(-\Delta) \) is an integral operator in \( L^2(\mathbb{R}^3) \) having the kernel

\[
G_z(x, x') = \frac{1}{(2\pi)^3} \int_{\mathbb{R}^3} \frac{e^{ip(x-x')}}{p^2 - z} \, dp = \frac{e^{i\sqrt{z}|x-x'|}}{4\pi|x-x'|}. \tag{5.3}
\]

Now we introduce the auxiliary Hilbert spaces \( \mathcal{H}_0 \equiv L^2(\mathbb{R}^2), \mathcal{H}_1 \equiv \mathbb{C}^n \) and abbreviate \( L^2 \equiv L^2(\mathbb{R}^3), W^{2,2} \equiv W^{2,2}(\mathbb{R}^3) \). By means of the trace maps \( \tau_0 : W^{2,2} \to \mathcal{H}_0 \) and \( \tau_1 : W^{2,2} \to \mathcal{H}_1 \) acting as

\[
\tau_0 f := f \mid_{\Lambda}, \quad \tau_1 f := f \mid_{\Pi} = (f \mid_{\{y(1)\}}, \ldots, f \mid_{\{y(n)\}}),
\]

we define in analogy with (2.3) the embeddings \( R_{iL}(z), R_{Li}(z), \) and \( r_{ji} \). The operator-valued matrix \( \Gamma(z) \) now takes the form

\[
\Gamma(z) = [\Gamma_{ij}(z) : \mathcal{H}_0 \oplus \mathcal{H}_1 \to \mathcal{H}_0 \oplus \mathcal{H}_1,
\]

where \( \Gamma_{ij}(z) : \mathcal{H}_i \to \mathcal{H}_j \) are the operators given by

\[
\Gamma_{ij}(z)g = -R_{ij}(z)g \quad \text{for} \quad i \neq j \quad \text{and} \quad g \in \mathcal{H}_j,
\]

\[
\Gamma_{00}(z)f = \left[ -\frac{i\sqrt{z}}{4\pi} \right] f \quad \text{if} \quad f \in \mathcal{H}_0,
\]

\[
\Gamma_{11}(z)\varphi = \left[ \left( \frac{\beta_l}{4\pi} \right) \delta_{kl} - G_z(y^{(k)}, y^{(l)})(1-\delta_{kl}) \right]_{k,l=1}^n \varphi \quad \text{for} \quad \varphi \in \mathcal{H}_1.
\]
To describe the inverse of $\Gamma(z)$ we introduce the reduced determinant $D(z) \equiv D_{11}(z) : \mathcal{H}_1 \rightarrow \mathcal{H}_1$ given again by $D(z) = \Gamma_{11}(z) - \Gamma_{10}(z)\Gamma_{00}(z)^{-1}\Gamma_{01}(z)$ for $z$ belonging to the resolvent set of $H_{\alpha,\beta}$. The inverse of $\Gamma(z)$ is given by $[\Gamma(z)]^{-1} : \mathcal{H}_0 \oplus \mathcal{H}_1 \rightarrow \mathcal{H}_0 \oplus \mathcal{H}_1$ defined as in (2.5). Calculations similar to those of Theorem 2.2 yield the resolvent formula for $z \in \rho(H_{\alpha,\beta})$ and $\text{Im } z > 0$ in the form

$$R_{\alpha,\beta}(z) \equiv (H_{\alpha,\beta} - z)^{-1} = R(z) + \sum_{i,j=0}^{1} R_{Li}(z)[\Gamma(z)]^{-1}_{ij}R_{jL}(z). \quad (5.4)$$

### 5.3 Spectrum of $H_{\alpha,\beta}$

Since the point interactions give rise to an explicit finite-rank perturbation to the resolvent, we find easily the absolutely continuous spectrum,

$$\sigma_{\text{ess}}(H_{\alpha,\beta}) = \sigma_{\text{ac}}(H_{\alpha,\beta}) = \left[-\frac{1}{4} \alpha^2, \infty\right).$$

As for the discrete spectrum we start again with the simplest case of a single point perturbation located at a distance $a$ from $\Lambda$; the coupling constant of this interaction is $\beta \in \mathbb{R}$. As we have said in the introduction we will concentrate only on the differences coming from the fact that the relative dimension of the two components of the interaction support is now two.

Let us denote by $H_{\beta} \equiv H_{0,\beta}$ the Laplace operator in $L^2$ with the perturbation supported at $y$ only. It is well known [2] that if $\beta < 0$ then the Hamiltonian $H_{\beta}$ has a single eigenvalue given by

$$\tilde{\epsilon}_{\beta} = -(4\pi \beta)^2.$$ 

In turn, if $\beta \geq 0$ the spectrum of $H_{\beta}$ has no isolated point. However, as we will see below, the operator $H_{\alpha,\beta}$ with $\alpha > 0$ has an eigenvalue even in the latter case. To derive spectral properties of $H_{\alpha,\beta}$ we have to find solutions of the equation $\tilde{D}(\kappa) = 0$ for $\kappa \in (\frac{1}{2} \alpha, \infty)$, where the operator $\tilde{D}(\kappa)$ now acts as the multiplication by the following function,

$$\tilde{d}_a(\kappa) := \beta + \frac{\kappa}{4\pi} - \tilde{\phi}_a(\kappa)$$

with

$$\tilde{\phi}_a(\kappa) := \frac{\alpha}{\pi} \int_{0}^{\infty} \frac{e^{-2(p^2 + \kappa^2)^{1/2}a}}{(2(p^2 + \kappa^2)^{1/2} - \alpha)(p^2 + \kappa^2)^{1/2}} p \, dp.$$
Since we want to investigate simultaneously the asymptotics of the eigenvalue for large and small $a$ it is convenient to put $H_{a,\beta,a} = H_{a,\beta}$. We have

**Theorem 5.1** For any $\alpha > 0$ and $\beta \in \mathbb{R}$ the operator $H_{a,\beta,a}$ has exactly one isolated eigenvalue $-\kappa_a^2 < -\frac{1}{4}\alpha^2$. Moreover, if $\beta > 0$ or $\tilde{\epsilon}_\beta \in \left[-\frac{1}{4}\alpha^2, \infty\right)$ then

$$-\lim_{a \to -\infty} \kappa_a^2 = \tilde{\epsilon}_\beta,$$

otherwise we have

$$-\lim_{a \to -\infty} \kappa_a^2 = -\frac{1}{4}\alpha^2.$$

In distinction to the two-dimensional situation we have now

$$-\lim_{a \to 0} \kappa_a^2 = -\infty.$$

**Proof.** The equations (5.5) and (5.6) can be obtained by mimicking the arguments employed in proofs of Thms 3.1 and 3.2. Using the explicit form for $\tilde{\phi}_a$ one can establish the existence of a positive $C$ such that $Ca^{-1} < \tilde{\phi}_a(\kappa)$. It follows that $\lim_{a \to 0} \tilde{\phi}_a(\kappa) = \infty$ which, in turn, implies (5.7).

**Remark 5.2** In the three-dimensional case one may say that the behaviour of the eigenvalue for large $a$ depends not only on the relation between $-\alpha^2/4$ and $\tilde{\epsilon}_\beta$; in the limit it is absorbed in the threshold also in the case when $\beta \geq 0$ and the discrete spectrum of $H_\beta$ is empty.

Proceeding similarly as in the proof of Theorem 3.5 arrive at

**Theorem 5.3** Let $\beta = (\beta_1, \ldots, \beta_n)$, where $\beta_i \in \mathbb{R}$ and $\alpha > 0$. Operator $H_{a,\beta}$ has at least one isolated eigenvalue and at most $n$. If all the numbers $-\beta_i$ are sufficiently large then $H_{a,\beta}$ has exactly $n$ eigenvalues.

### 5.4 Resonances

To recover the resonances for the model in question we can proceed similarly as in Sec. 4.1. Assume that $\beta < 0$ and $\tilde{\epsilon}_\beta > -\alpha^2/4$. In analogy with Lemma 4.1 we state that the resolvent of $H_{a,\beta}$ has a second-sheet continuation through the interval $(-\frac{1}{4}\alpha^2, 0)$. Let us put $\tilde{\varsigma}_\beta := \sqrt{-\tilde{\epsilon}_\beta} = 4\pi\beta$. 

27
Theorem 5.4 Assume $\tilde{\epsilon}_\beta > -\frac{1}{4} \alpha^2$. For any $a$ sufficiently large the resolvent $R_{\alpha, \beta}$ has the second sheet pole at a point $z(a)$ with the real and imaginary part, $z(a) = \mu(a) + i\nu(a)$, $\nu(a) < 0$, which in the limit $a \to \infty$ behave in the following way,

$$\mu(a) = \tilde{\epsilon}_\beta + O(e^{-a\tilde{\varsigma}_\beta}), \quad \nu(a) = O(e^{-a\tilde{\varsigma}_\beta}).$$  \hfill (5.8)

Remark 5.5 The resonance pole exists even if the distance is not large. In contrast to the two dimensional case, however, the imaginary part of the pole position $\nu(a)$ diverges to $-\infty$ as $a \to 0$.

Appendix A: Proof of Lemma 4.1

In view of the edge-of-the-wedge theorem, our aim is to show that

$$\lim_{\epsilon \to 0^+} \phi_a^\pm(\lambda \pm i\epsilon) = \phi_a^0(\lambda) \quad \text{for} \quad -\frac{1}{4} \alpha^2 < \lambda < 0. \quad (A.1)$$

Given $\epsilon > 0$ we put $z_\lambda^\pm(\epsilon) := \lambda \pm i\epsilon$. Let $\delta(\cdot)$ be function of the parameter $\epsilon$ such that $0 < \delta(\epsilon) < \epsilon$. We use them to define a family of the sets $C_i^\pm(\epsilon)$ in the complex plane, each of which may be regarded as a graph of a curve,

$$C_1^\pm(\epsilon) \equiv C_i^\pm(\epsilon) := \{w = x : x \in [\delta(\epsilon), \epsilon^{-1}]\},$$

$$C_2^\pm(\epsilon) := \{w = x \pm i\epsilon : x \in [0, x_2] \cup [x_1, \epsilon^{-1}]\}$$

with

$$x_k \equiv x_k(\epsilon) := \lambda + \frac{1}{4} \alpha^2 + (-1)^{k+1} \delta(\epsilon), \quad k = 1, 2;$$

furthermore,

$$C_3^\pm(\epsilon) := \{w = z^\pm(\epsilon) + \frac{1}{4} \alpha^2 + \delta(\epsilon)e^{i\theta} : \theta \in \pm[0, \pi]\},$$

$$C_4^\pm(\epsilon) := \{w = \epsilon^{-1} \pm iy : \epsilon \in [0, \epsilon]\} \cup \{w = \pm iy : \epsilon \in [\delta(\epsilon), \epsilon]\},$$

$$C_5^\pm(\epsilon) := \{w = \delta(\epsilon)e^{i\theta} : \pm \theta \in [0, \frac{1}{4}\pi]\}.$$

It is easy to see that from the definitions of $C_i^\pm(\epsilon)$ that each of their unions,

$$C^\pm(\epsilon) := \sum_{i=1}^5 C_i^\pm(\epsilon),$$

28
is a graph of a closed curve in the closed upper and lower complex halfplane, respectively, and that the regions encircled by these loops do not contain singularities of the functions \( w \mapsto \mu(\pm \lambda (\varepsilon), w)(w - z^\pm(\varepsilon) - \frac{1}{4}\alpha^2)^{-1} \); thus by the basic theorem about analytic functions we have

\[
\int_{C^\pm(\varepsilon)} \frac{\mu(\pm \lambda (\varepsilon), w)}{w - z^\pm(\varepsilon) - \frac{1}{4}\alpha^2} \, dw = 0.
\] (A.2)

This will be our starting point to check the relation (A.1):

1st step: Since by assumption \( \delta(\varepsilon) \to 0 \) as \( \varepsilon \to 0^+ \) so \( C_1(\varepsilon) \) approaches the positive real halfline, the limits we want to find are equal

\[
\lim_{\varepsilon \to 0^+} \phi^+_a(z^+(\varepsilon)) = \lim_{\varepsilon \to 0^+} \int_{C_1(\varepsilon)} \frac{\mu(z^+(\varepsilon), w)}{w - z^+(\varepsilon) - \frac{1}{4}\alpha^2} \, dw
\]

and

\[
\lim_{\varepsilon \to 0^+} \phi^-_a(z^-(\varepsilon)) = \frac{1}{\pi i} \left( \int_{C_1(\varepsilon)} \frac{\mu(z^-(\varepsilon), w)}{w - z^-(\varepsilon) - \frac{1}{4}\alpha^2} \, dw + g_{\alpha,a}(z^-(\varepsilon)) \right).
\]

2nd step: Consider next the integration over \( w^\pm = t \pm i\eta(\varepsilon) \in C_2^\pm(\varepsilon) \).

Using the following obvious convergence relations,

\[
(z^\pm(\varepsilon) - w^\pm)^{1/2} \to i(t - \lambda)^{1/2} \quad \text{as} \quad \varepsilon \to 0,
\]

\[
\sqrt{w^\pm} \to \pm \sqrt{t} \quad \text{as} \quad \varepsilon \to 0,
\]

we find

\[
\lim_{\varepsilon \to 0^+} \int_{C_2^\pm(\varepsilon)} \frac{\mu(z^\pm(\varepsilon), w^\pm)}{w^\pm - z^\pm(\varepsilon) - \frac{1}{4}\alpha^2} \, dw^\pm = \pm \mathcal{P} \int_0^\infty \frac{\mu^0(\lambda, t)}{t - \lambda - \frac{1}{4}\alpha^2} \, dt.
\] (A.3)

3rd step: In the integration over the circular segments around the poles away of the origin, \( w^\pm \in C_3^\pm(\varepsilon) \), we employ the convergence

\[
(z^\pm(\varepsilon) - w^\pm)^{1/2} \to \frac{i}{2} \alpha \quad \text{as} \quad \varepsilon \to 0,
\]

\[
\sqrt{w^\pm} \to \sqrt{\lambda + \frac{1}{4}\alpha^2} \quad \text{as} \quad \varepsilon \to 0,
\]

which yields

\[
\mu(z^\pm(\varepsilon), w^\pm) \to \pm \frac{g_{\alpha,a}(\lambda)}{\pi i} \quad \text{as} \quad \varepsilon \to 0.
\] (A.4)
To proceed further we use the following identities

\[
\int_{C_{\pm}(\varepsilon)} \frac{\mu(z_{\pm}^{\pm}(\varepsilon), w^{\pm})}{w^{\pm} - z_{\pm}^{\pm}(\varepsilon) - \frac{1}{4}\alpha^2} \, dw^{\pm} = \pm \frac{g_{\alpha,\alpha}(\lambda)}{\pi i} \int_{C_{\pm}(\varepsilon)} \frac{1}{w^{\pm} - z_{\pm}^{\pm}(\varepsilon) - \frac{1}{4}\alpha^2} \, dw^{\pm} \\
+ \int_{C_{\pm}(\varepsilon)} \frac{\mu(z_{\pm}^{\pm}(\varepsilon), w^{\pm}) \mp g_{\alpha,\alpha}(\lambda)(\pi i)^{-1}}{w^{\pm} - z_{\pm}^{\pm}(\varepsilon) - \frac{1}{4}\alpha^2} \, dw^{\pm}.
\]

Since \( \lim_{\varepsilon \to 0} \int_{C_{\pm}(\varepsilon)} \frac{1}{w^{\pm} - z_{\pm}^{\pm}(\varepsilon) - \frac{1}{4}\alpha^2} \, dw^{\pm} = \mp \pi i \), the limit as \( \varepsilon \to 0^+ \) of the first component in the above relation equals \( \pm g_{\alpha,\alpha}(\lambda) \). Moreover, in view of the convergence (A.4) and the fact that the functions involved are continuous at the segment in question we can find a function \( \varepsilon \mapsto \zeta(\varepsilon) \) such that \( \zeta(\varepsilon) \to 0 \) as \( \varepsilon \to 0 \) and \( \left| \mu(z_{\pm}^{\pm}(\varepsilon), w^{\pm}) \mp g_{\alpha,\alpha}(\lambda)(\pi i)^{-1} \right| < \zeta(\varepsilon) \) for \( w^{\pm} \in C_{3}(\varepsilon) \). Then

\[
\int_{C_{\pm}(\varepsilon)} \left| \frac{\mu(z_{\pm}^{\pm}(\varepsilon), w^{\pm}) \mp g_{\alpha,\alpha}(\lambda)(4i)^{-1}}{w^{\pm} - z_{\pm}^{\pm}(\varepsilon) - \frac{1}{4}\alpha^2} \right| \, dw^{\pm} < \pi \zeta(\varepsilon),
\]

i.e. the second integral in the above identity vanishes as \( \varepsilon \to 0 \). Summarizing the argument we get

\[
\lim_{\varepsilon \to 0^+} \int_{C_{\pm}(\varepsilon)} \frac{\mu(z_{\pm}^{\pm}(\varepsilon), w^{\pm})}{w^{\pm} - z_{\pm}^{\pm}(\varepsilon) - \frac{1}{4}\alpha^2} \, dw^{\pm} = -g_{\alpha,\alpha}(\lambda).
\]

4th and 5th step: Next we note that the limit \( \left| w^{\pm} \frac{\mu(z_{\pm}^{\pm}(\varepsilon), w^{\pm})}{w^{\pm} - z_{\pm}^{\pm}(\varepsilon) - \frac{1}{4}\alpha^2} \right| \) as \( \varepsilon \to 0 \) implies for the integral over the “vertical” parts of the integration curve

\[
\lim_{\varepsilon \to 0^+} \int_{C_{\pm}(\varepsilon)} \frac{\mu(z_{\pm}^{\pm}(\varepsilon), w^{\pm})}{w^{\pm} - z_{\pm}^{\pm}(\varepsilon) - \frac{1}{4}\alpha^2} \, dw^{\pm} = 0.
\]

Finally, it is also easy to see that the remaining integral over \( C_{3}(\varepsilon) \) vanishes in the limit \( \varepsilon \to 0 \). Combining (A.2) with the above results we get

\[
\lim_{\varepsilon \to 0^+} \phi_{\alpha}^{\pm}(z_{\pm}(\varepsilon)) = \phi_{\alpha}^{0}(\lambda),
\]

so the function \( \phi_{\alpha}^{0} \) is continuous for \( \lambda \in (-\frac{1}{4}\alpha^2, 0) \) and the proof is complete.

**Appendix B: Lippmann–Schwinger equation**

Here we present another possible approach to the scattering problem which we have discussed in Sec. 4.3.
2.4.1 Additive representation of $H_{\alpha,\beta}$

It is also useful to write $H_{\alpha,\beta}$ in an additive form which would be reminiscent of the usual potential interaction – cf. [15, 16, 17]. To this aim, let us construct for the operator $\tilde{H}_{\alpha} : D(\tilde{H}_{\alpha}) \to L^2$ the natural rigged Hilbert space, i.e. the triplet

$$\mathcal{H}_{\alpha;\mp} \supset L^2 \supset \mathcal{H}_{\alpha;\pm},$$

where $\mathcal{H}_{\alpha;\pm}$ are the completion of $D(\tilde{H}_{\alpha})$ in the norm

$$\|f\|_{\pm} := \|(\tilde{H}_{\alpha} - \lambda)^{\mp\frac{1}{2}} f\|,$$  

where $\lambda < -\frac{1}{4} \alpha^2$.

Then we can define the extension of $\tilde{H}_{\alpha}$ to whole $L^2$; this leads to the map $H_{\alpha} : L^2 \to \mathcal{H}_{\alpha;\pm}$ which expresses the canonical unitarity between $L^2$ and $\mathcal{H}_{\alpha;\pm}$. Let $D(V_{\beta})$ denote the set of functions $f \in W^{1,2}_{\text{loc}}(\mathbb{R}^2 \setminus (\Sigma \cup \Pi)) \cap L^2$ such that the limits $\Xi_{\Sigma}(f)$, $\Omega_{\Sigma}(f)$ satisfy (2.1) and $\Xi_{i}(f)$, $\Omega_{i}(f)$ are finite.

Now we define the operator $V_{\beta} : D(V_{\beta}) \to \mathcal{H}_{\alpha;\pm}$ by

$$V_{\beta}\psi = \sum_{i=1}^{n} \psi_{\beta}^{\beta_{i}} \delta(\cdot - y^{(i)}) , \quad \text{where} \quad \psi_{\beta}^{\beta_{i}} := \begin{cases} - (2\pi \beta_{i})^{-1} \Omega_{i}(\psi) & \text{if} \ \beta \neq 0 \\ - \Xi_{i}(\psi) & \text{if} \ \beta = 0 \end{cases}$$

Let us note that since $R_{\alpha;L1} = \sum_{i=1}^{n} G_{\alpha}^{\beta}(\cdot - y^{(i)}) \in L^2$ the operator $V_{\beta}$ is indeed well defined as a map acting to $\mathcal{H}_{\alpha;\pm}$. Now we can define the sought operator,

$$\tilde{H}_{\alpha} + V_{\beta} : D(\tilde{H}_{\alpha} + V_{\beta}) \to L^2, \quad (\tilde{H}_{\alpha} + V_{\beta})f = H_{\alpha}f + V_{\beta}f , \quad (B.1)$$

with the domain given by

$$D(\tilde{H}_{\alpha} + V_{\beta}) = \{ g \in D(V_{\beta}) : H_{\alpha}g + V_{\beta}g \in L^2 \}.$$  

With this notations we have the following result.

**Lemma B.1** $H_{\alpha,\beta} = \tilde{H}_{\alpha} + V_{\beta}$.

**Proof.** It is easy to see that $H_{\alpha}g + V_{\beta}g \in L^2$ if and only if $g \in D(\tilde{H}_{\alpha,\beta})$ because only the boundary conditions given by (2.1) ensure the appropriate compensation of $\delta(\cdot - y^{(i)})$ induced by $V_{\beta}$ – cf. [16]. At the same time, it is also easy to see that $(\tilde{H}_{\alpha} + V_{\beta})g(x) = \tilde{H}_{\alpha}g(x)$ for $x \in \mathbb{R}^2 \setminus \Pi$; this completes the proof. ■
2.4.2 Generalized Lippman–Schwinger equation

In the same vein we want to find now an analog of the Lippman–Schwinger equation – cf. [1]. The additive representation (B.1) provides an inspiration: it is reasonable to expect that the generalized eigenvectors $\psi_\lambda^\pm$ of $H_{\alpha,\beta}$ will satisfy

$$
\psi_\lambda^\pm = \omega_\lambda - R_{\alpha}^\pm(\lambda)V_\beta\psi_\lambda^\pm \quad \text{for} \quad \lambda \in \left[-\frac{1}{4}\alpha^2, \infty\right),
$$

(B.2)

where $\omega_\lambda = \lim_{\varepsilon \to 0} \omega_{\lambda+i\varepsilon}$ are the generalized eigenvectors of $H_\alpha$ introduced in Sec. 4.3.1 and $R_{\alpha}^\pm(\lambda)$ are the limits $\lim_{\varepsilon \to 0^+} R_{\alpha}(\lambda\pm i\varepsilon)$ in a suitable generalized sense. We have to emphasize that the equation (B.2) has only a formal meaning; our aim is now to replace it by a mathematically rigorous object. For $z^\pm(\varepsilon) = \lambda \pm i\varepsilon$ define functions $\psi_{z^\pm(\varepsilon)} \in L^2$ by

$$
\psi_{z^\pm(\varepsilon)} := (H_{\alpha,\beta} - z^\pm(\varepsilon))^{-1}(\tilde{H}_\alpha - z^\pm(\varepsilon))\omega_{z^\pm(\varepsilon)},
$$

(B.3)

i.e. the limits $\psi_{\lambda}^\pm := \lim_{\varepsilon \to 0} \psi_{z^\pm(\varepsilon)}$ in the distributional sense constitute the generalized eigenvalues of $H_{\alpha,\beta}$. Furthermore, a direct calculation shows the following relation

$$
\psi_{z^\pm(\varepsilon)} := \omega_{z^\pm(\varepsilon)} - R_{\alpha}(z^\pm(\varepsilon))V_\beta\psi_{z^\pm(\varepsilon)}.
$$

(B.4)

which after taking the distributional limit $\varepsilon \to 0$ gives the strict meaning to heuristic relation (B.2). Of course, the limits $\psi_{\lambda}^\pm$ belong only locally to $L^2$, however, they satisfy the same boundary conditions on $\Sigma \cup \Pi$ as functions from $D(H_{\alpha,\beta})$. This allows us to construct the extension $\tilde{V}_\beta$ of $V_\beta$ to $\psi_{\lambda}^\pm$ because the latter “feels” only the behaviour of functions on $\Pi$. With this notation the relation (B.4) after taking the limit $\varepsilon \to 0$ acquires the following form,

$$
\psi_{\lambda}^\pm = \omega_{\lambda} - R_{\alpha}(\lambda)\tilde{V}_\beta\psi_{\lambda}^\pm.
$$

(B.5)
